DECUS Program Library Write-up

DECUS No. 8-130B

1. ABSTRACT

RELCON converts standard DEC binary program tapes to a relocatable form acceptable to the Rebil8 loader.

- 2. REQUIREMENTS
- 2.1 Storage

The program uses 600 octal memory locations.

2.2 Equipment

Minimum - PDP8/S and ASR-33.

- 3. USAGE
- 3.1 Loading

The program is supplied as a relocatable binary tape and is loaded by Rebil8.

Place RELCON in the tape reader and switch the reader ON.

Place 7777 in the Switch Register and press Load Address.

Place the memory address at which RELCON will start loading, then press Start. Refer to Rebil8 write-up for further information regarding relocatable program loading.

3.2 Switch Settings

Leave the Switch Register as set, but ensure that the SR bits 5-11 are zero's. The Switch Register now contains RELCON's starting address.

Note: If the Switch Register contained 7777, re-set the register to 0000.

3.3 Start Up

Place the Address List in the reader and switch the reader ON. At installations having two tape readers, switch the second reader OFF. Switching the reader OFF LINE or removing tape from the reader will suffice.

Press Load Address, then press Start.

If the computer halts before the list is exhausted, a format error has been detected. Rectify the fault and repeat step 3.3.

3.4 DEC Binary Tape Reading

Place the DEC binary tape in the reader and switch the reader ON.

Note: RELCON copies leader/trailer code, so that the length of L/T produced by the punch is dependent on the length of L/T read.

Press the Continue key and the DEC binary tape is read and converted.

If the computer fails to run, a format error detected during step 3.3 has been overlooked. Correct the faulty list and repeat step 3.3

If the trailer code fails to copy, an error has occured during DEC binary tape reading. Reposition the tape and repeat step 3.4.

4. DESCRIPTION

4.1 Discussion

It is suggested that reference is made to Rebil8 write-up for a discussion on Address Modification and Data Modification before continuing.

The principal duty of RELCON is to tag data, used by memory reference instructions for indirect addressing, with the Data Modification Mark (376 Code). It will, if required, also adjust addresses so that the relocatable version commences loading memory at page 0 if no Address modification is specified. This does not necessarily mean that the program will, or can, operate in this area of memory, but serves to simplify address specification at load time.

For example, an unconverted binary program tape normally loading memory from location 5400, is converted to a relocatable tape with addresses justified to page 0. To load this program at location 1000, the absolute memory address (1000) is used as the Address Modification.

If the program is not justified to page 0, an Address Modification of 3400 (-4400) core locations would be used to load the program at address 1000.

4.2 The Address List

The list contains the lowest address occupied by the unconverted program, and the addresses of data to be tagged with the Data Modification Mark.

If addresses are not to be page 0 justified, the lowest address is specified as 0 (*0).

5. LIST FORMAT

5.1 List Structure

An address list is shown in the following example -

*200	241	605	777	1063	1065	1066
1066	310	0437	\$			

The asterisk denotes the following octal number is the lowest address to be found on the DEC binary tape. The remaining numbers represent the addresses of data to be tagged with the 376 code.

The dollar sign terminates the list.

Numbers may be preceded by and are terminated by spaces, carriage return, line feed, and Leader/Trailer.

Deleted characters are ignored.

5.2 Errors

An error is detected during List reading if one of the following conditions occur.

The numeral 8 or 9, or characters not mentioned above appear in the List.

The asterisk does not preceed the first encountered number.

An asterisk appears elsewhere in the List.

The List contains more than 136 data addresses.

5.3 A program requiring conversion to relocatable binary but not containing out-of-page memory references must be accompanied by a list similar to that shown below.

* XXXX 0 \$

where * XXXX represents the lowest address on the unconverted tape, and 0 indicates no address list.

Failure to comply with the above can result in spurious data modification marks appearing on the relocatable binary tape.
